

## Simple linear regression in EViews

---

### *Econometrics for Financial Markets*

#### Learning goals:

- Understand how to run a simple regression in EViews.
- Use EViews to interpret regression output and test basic hypotheses
- Know how to calculate hedging ratios
- Understand how to calculate asset alphas and betas and how you can test whether a portfolio has a significant abnormal return.

#### Literature

- Brooks, Chapter 3. A brief overview of classical linear regression

#### Background Reading

- Brealey, Myers and Allen, *Principles of Corporate Finance*  
Chapter 8. Portfolio Theory and Capital Asset Pricing Model (Ch8.2-8.4)
- Eviews Tutorials, <http://www.eviews.com/Learning/index.html>

In this eviews class we are going to use simple regressions to (i) calculate hedging ratios and (ii) calculate the beta of a stock using the Capital Asset Pricing Model (CAPM).

## Data Set 1: Calculating an optimal hedge ratio.

### Task 1 Start Eviews and Import Data

- a) **Import** SandPhedge.xls; This file can be found on the Moodle
- b) **Generate** a new series that represents the log returns for the spot and futures

$$r = \ln(P_t) - \ln(P_{t-1}) = \Delta \ln(P_t)$$

### Task 2 Descriptive Analysis of Data

- a) Create a **group** containing the Spot and Futures return data
- b) check the **descriptive statistics** of the Spot and Futures return data
- c) create line and scatter **graphs** containing the Spot and Futures return data

### Task 3 Calculating the Hedge Ratio

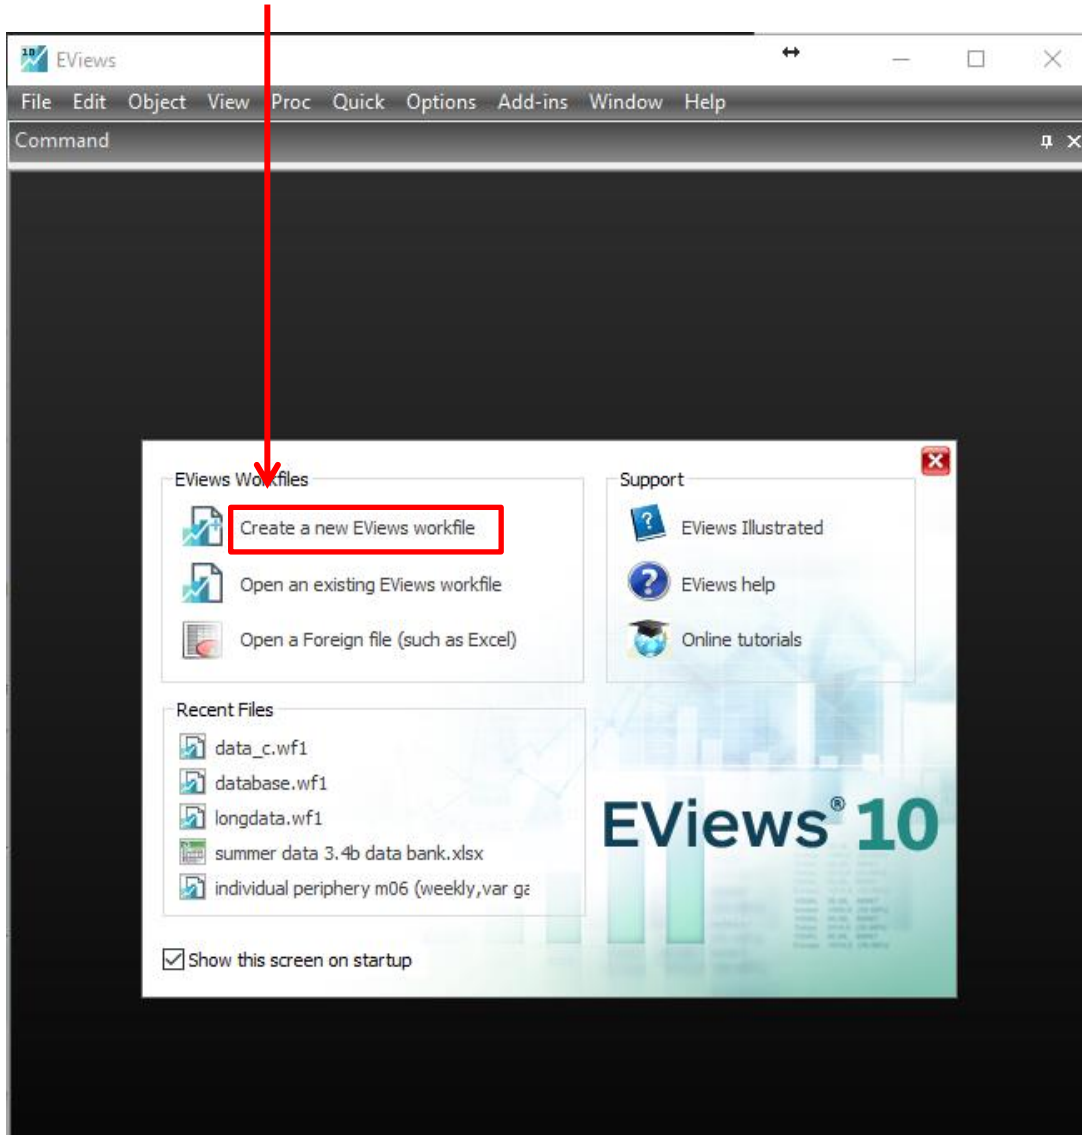

- a) **Estimate** the following regression:  $r_s = \alpha + \beta r_f + \epsilon$  and save the regression output, where  $r_s$  is the spot return and  $r_f$  is the futures return.
- b) **Test** the null hypothesis that  $\alpha = 0$  and  $\beta = 0$  for both the returns regression
- c) **Test** the null hypothesis that  $\beta = 1$  for the returns regression
- d) **Interpret** your results

## Solutions 1: Calculating an optimal hedge ratio.

### Task 1 Start EViews and Import Data

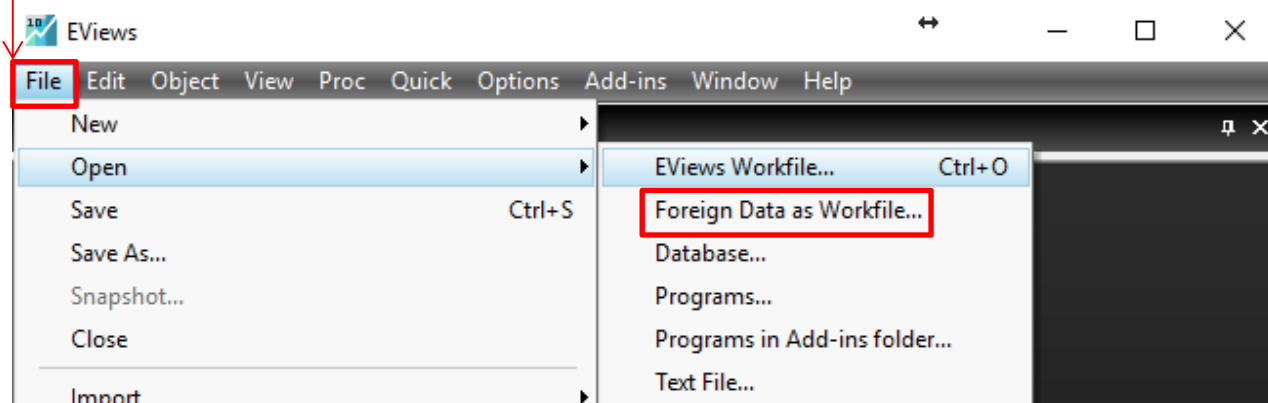

#### a) Import SandPhedge.xls

To import an excel file or other format of data into eviews, you can either click **create a new Eviews workfile** on the start up screen of eviews

Or go to

**File\Open\Foreign Data as Wokfile...**

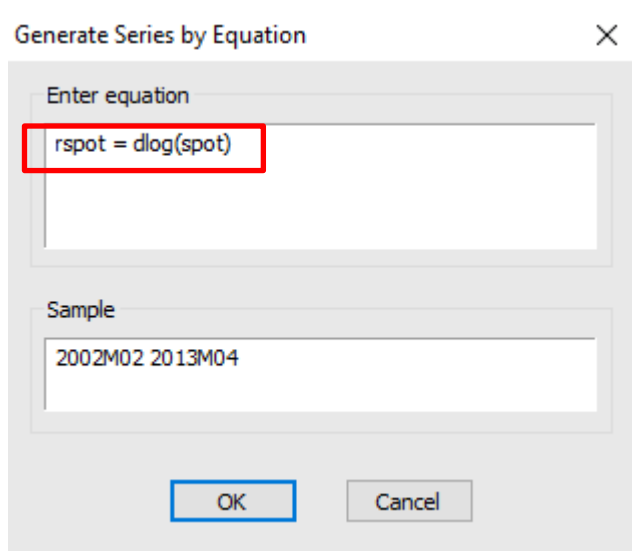

**b) Generate** new series that represent log returns for the spot and futures

To manipulate your data and create a transformed series from your original data go to

**Object\Generate Series\...** and type the desired equation in the windows that pops up.

On the LHS of the equation you type the name of the variable you want to create and on the RHS the formula. Two common functions that are used are  $\ln P = \log(P)$  to create the natural logs of a variable and  $\text{ret} = \text{dlog}(P)$  which calculates  $\Delta \ln P = \ln P_t - \ln P_{t-1}$ .

Alternatively, you can write commands straight in the command window. The command series will create a new series which has a name the first input you give and as definition the part to the right of the equal sign. So entering

**Series rfutures = dlog(futures)** will create a new series called **rfutures** which is defined as the log return (log difference) of the series `futures`

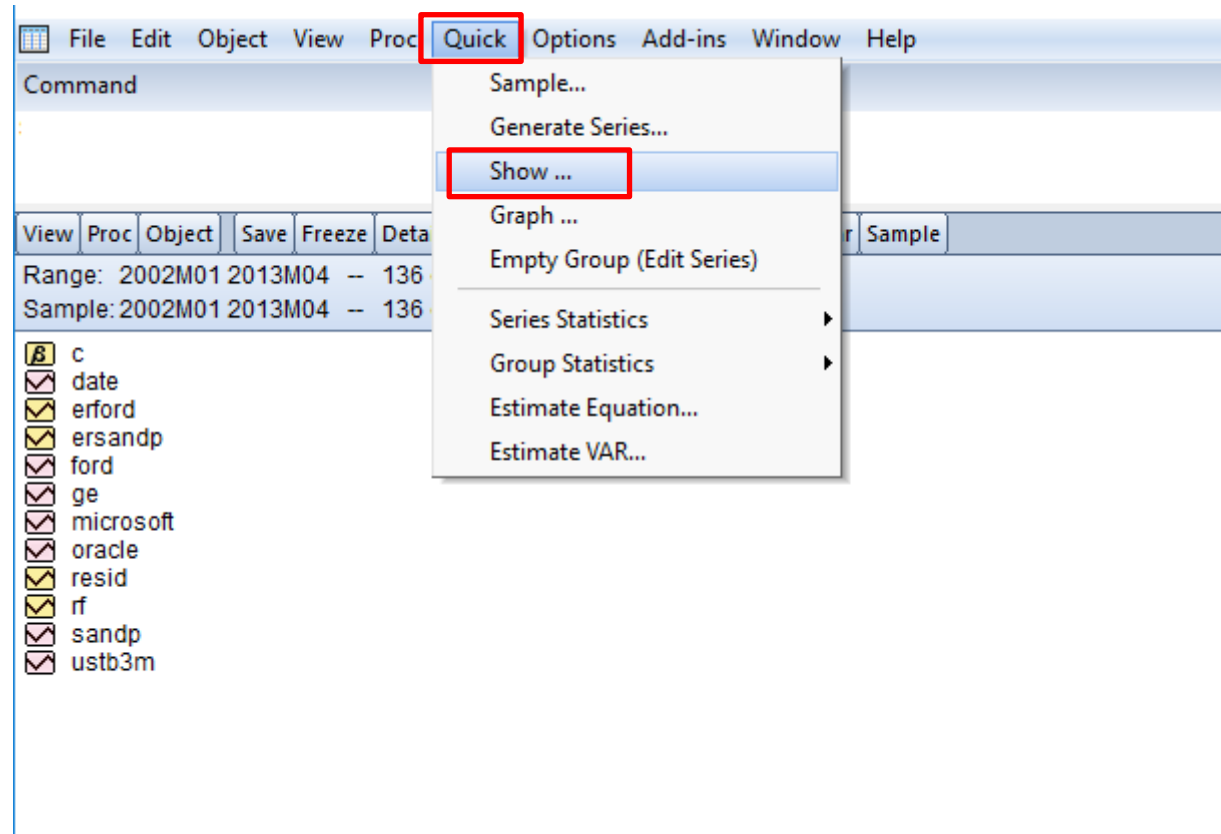

## Task 2 Descriptive Analysis of Data

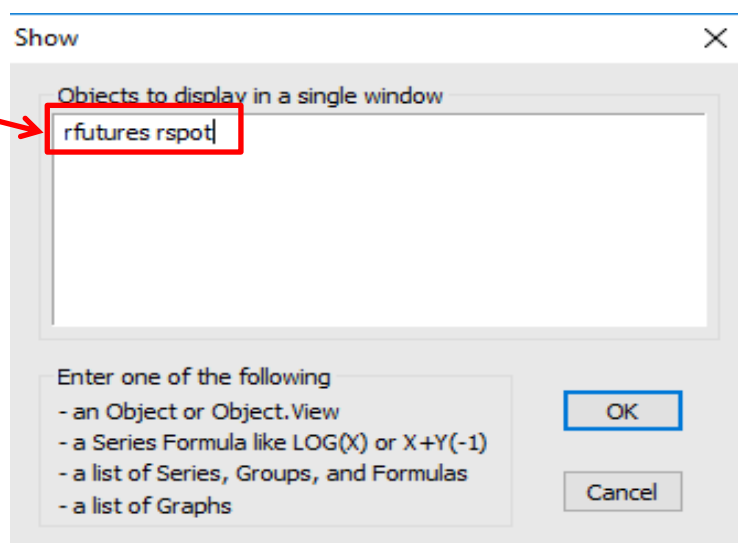

### a) Create a **group** containing the Spot and Futures return data

The object `group` is very useful to perform operations on multiple series simultaneously. We will use it here to get summary statistics and graphs for all variables at the same time. Like most things in eviews, there are several ways to create a new group: via the menu or via a command.

A new group can be created via the menu option **Quick\Show...** and type the the series you want to include in the group in the window that pops up.

Type:  
rfutures  
rspot

Alternative you can type **group g1 rfutures rspot** in the command line, which will create a group object called g1 containing the series rfutures and rspot.

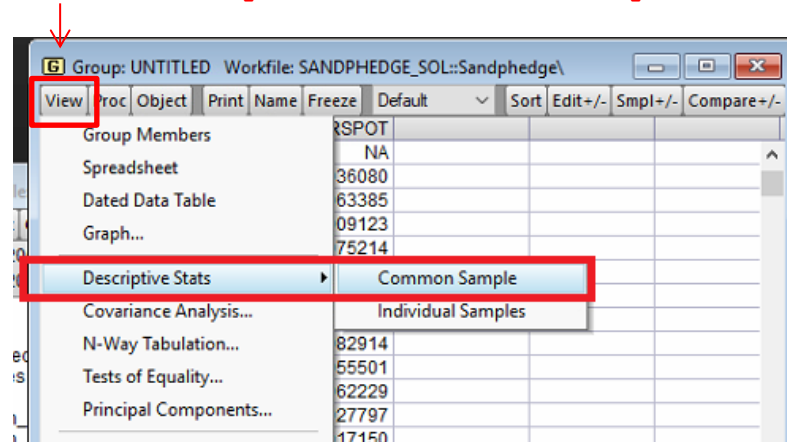

To name your series and make it a permanent object click on the **name** button in the group window should be open now.

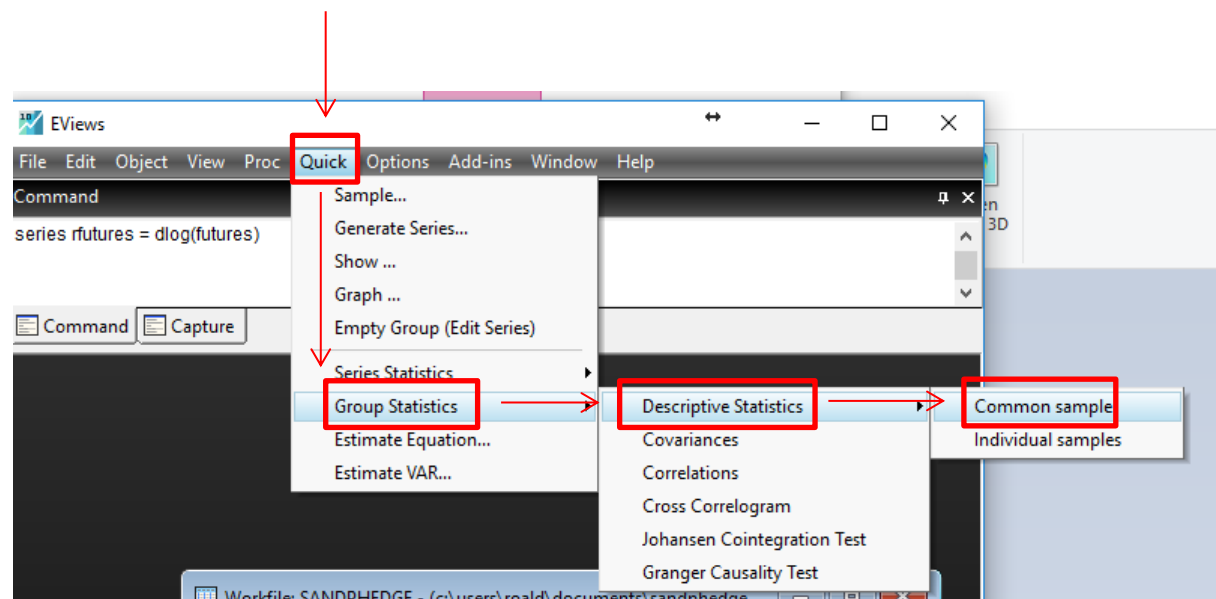

b) check the **descriptive statistics** of the Spot and Futures return data

One of the advantages of a group is that you can get summary statistics of all series simultaneous. You can access the summary statistics by opening the group window and clicking on **View\Descriptive Stats\Common Sample**

or through the main ribbon via

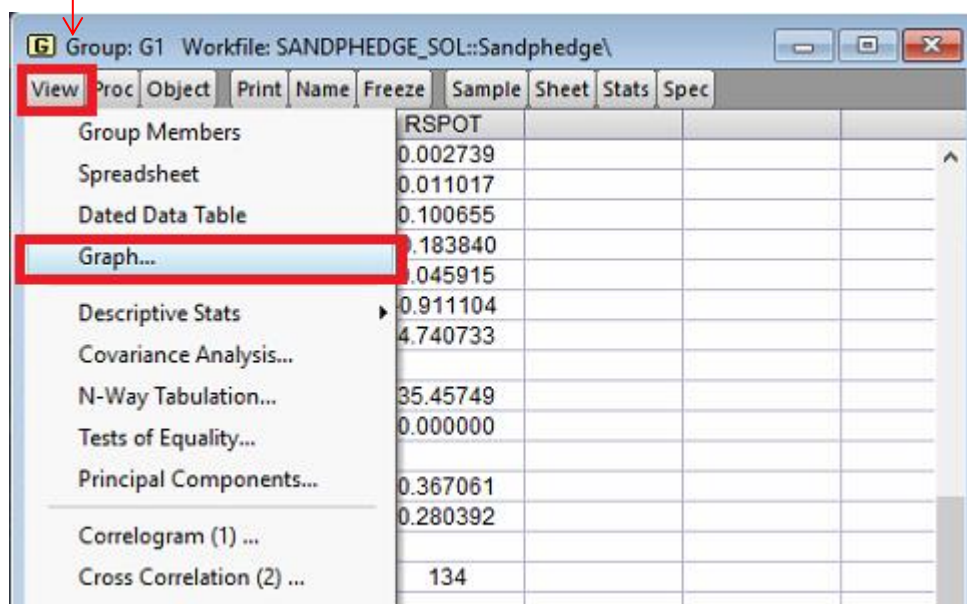

**Quick\Group Statistics\Descriptive\Common sample**

The screenshot shows the EViews Group window displaying the results of the Descriptive Statistics command. The results are presented in a table with columns for the series (RFUTURES and RSPOT) and rows for various statistical measures. The 'Observations' row shows 134 observations for both series.

	RFUTURES	RSPOT
Mean	0.002713	0.002739
Median	0.010248	0.011017
Maximum	0.103912	0.100655
Minimum	-0.188026	-0.183840
Std. Dev.	0.045481	0.045915
Skewness	-0.927525	-0.911104
Kurtosis	4.878594	4.740733
Jarque-Bera	38.91766	35.45749
Probability	0.000000	0.000000
Sum	0.363553	0.367061
Sum Sq. Dev.	0.275117	0.280392
Observations	134	134

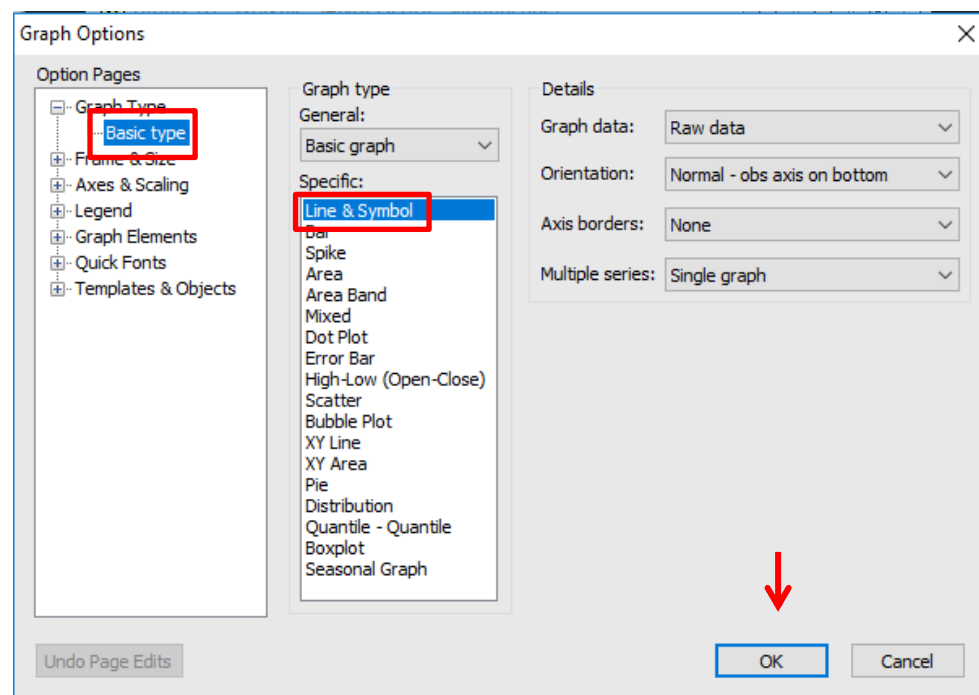

- c) Create line and scatter **Graphs** containing the Spot and Futures return data  
 Graphs can be created through objects as well. For a graph of a single series, to create a multiple graph, open a group; then click on **View\Graph...**

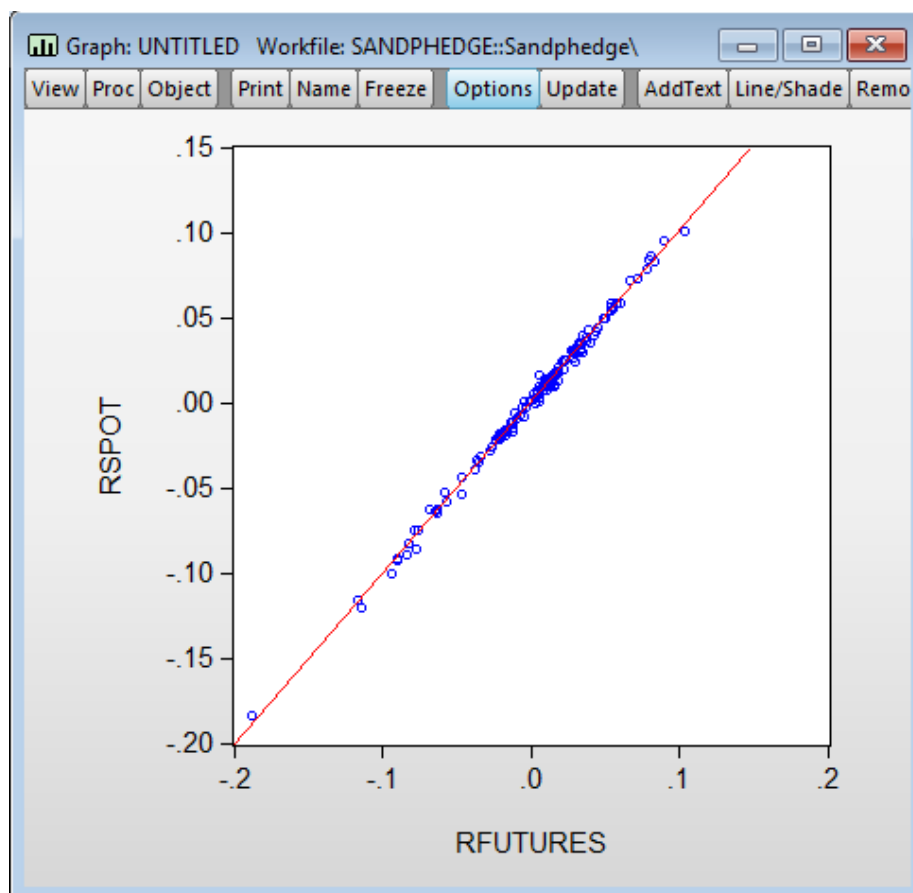

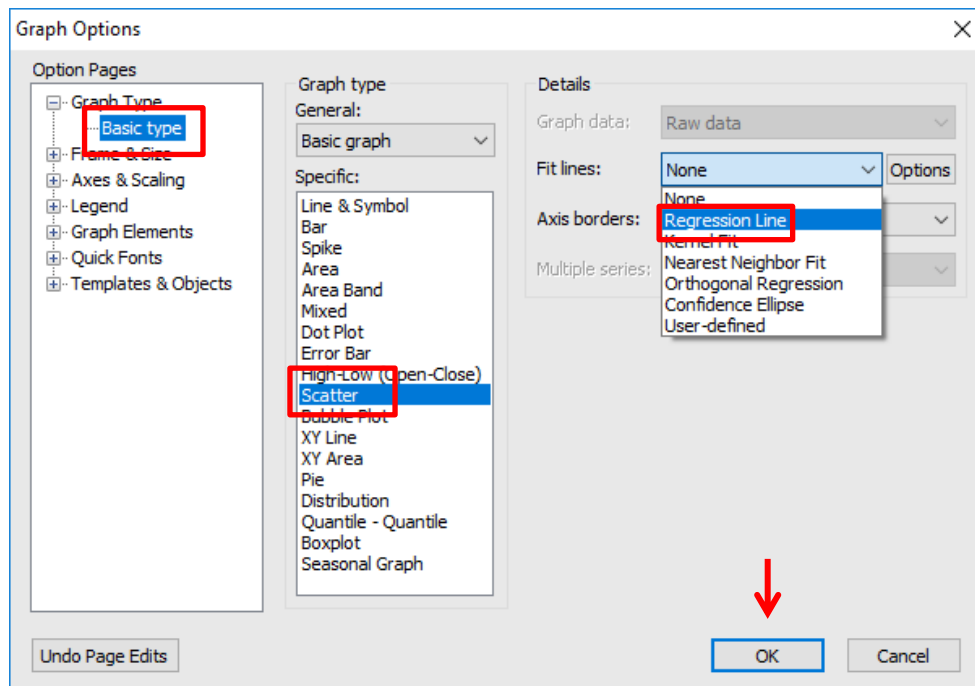

After you click on this the graph a window pops up which a large host of options to create graphs. Most important is the column in the middle which allows you to set the type of graph you want to create. This will be shown below.

Alternatively you can use the command window to request graphs. Examples of command line commands to create graphs are

First lets create a line graph, which is selected as default.

To create a scatter select the option scatter. You can add a fit line by changing the options on the RHS (see picture below)

### Task 3 Calculating the Hedge Ratio

- a) **Estimate** the following regression:  $r_s = \alpha + \beta r_f + \epsilon$  and save the regression output, where  $r_s$  is the spot return and  $r_f$  is the futures return.

To estimate an equation, click on **Quick\Estimate Equation\...**

A window will open with all the estimation options. As innocent as it looks, it is probably the most important window in Eviews. The top half of the window contains the equation you are to estimate, and the bottom half allows you to change the estimation method and the sample. For now let's leave the estimation method unchanged. The equation in the top half takes some getting use to. The syntax is as follows: **[dependent variable] [constant] [independent variables]**

So to estimate:

$$rspot_t = \alpha + b \times rfutures_t + \epsilon_t$$

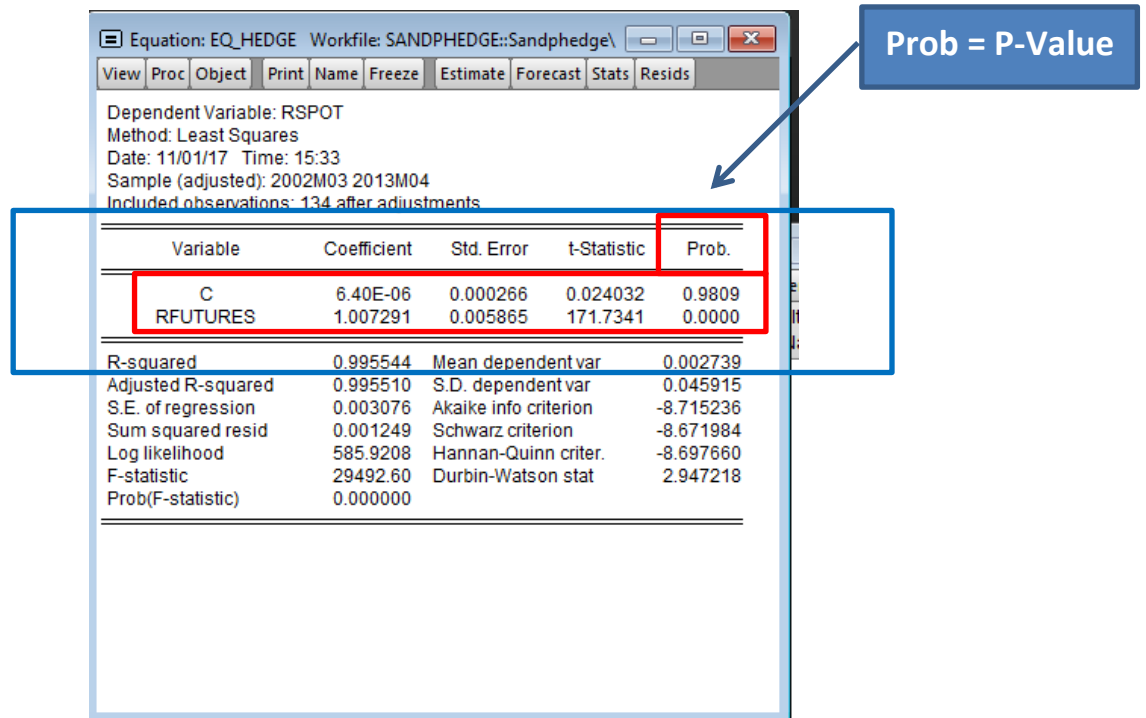

you type inside the box:

The image shows a screenshot of the EViews software interface. On the left, the 'Quick' menu is open, with 'Estimate Equation...' highlighted. A red box is drawn around the 'Quick' menu header. Above the menu, a text box contains the equation 'rspot c rfutures', with a red arrow pointing from it to the 'Equation specification' field in the 'Estimate Equation' dialog box. The dialog box has two tabs: 'Specification' and 'Options'. The 'Specification' tab is active, showing the 'Equation specification' field with the text 'rspot c rfutures'. Below this, the 'Estimation settings' section shows 'Method: LS - Least Squares (NLS and ARMA)' and 'Sample: 2002M02 2013M04'. Red boxes are drawn around the 'Equation specification' field and the 'Sample' field. At the bottom right of the dialog box are 'OK' and 'Cancel' buttons. A red arrow points from the 'Equation specification' field to the 'Sample' field.

**b) Test the null hypothesis that  $\alpha = 0$  and  $\beta = 0$  for both the returns regression**

The blue box contains all the information you need. The t-Statistic and Prob. Are the tstat and the **p-val** associated with the hypothesis that the associated coefficient is equal to zero.

As you can see, the p-value for the constant is very high (well above the threshold of 0.05) and the p-value for **RFUTURES** is very low (well below the threshold of 0.05). So we conclude that we cannot reject the null that the constant is zero, but we *can* reject the null that beta is zero.

Equation: EQ\_HEDGE Workfile: SANDPHEDGE::Sandphedge\

View Proc Object Print Name Freeze Estimate Forecast Stats Resids

Dependent Variable: RSPOT  
Method: Least Squares  
Date: 11/01/17 Time: 15:33  
Sample (adjusted): 2002M03 2013M04  
Included observations: 134 after adjustments

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	6.40E-06	0.000266	0.024032	0.9809
RFUTURES	1.007291	0.005865	171.7341	0.0000

R-squared 0.995544 Mean dependent var 0.002739  
Adjusted R-squared 0.995510 S.D. dependent var 0.045915  
S.E. of regression 0.003076 Akaike info criterion -8.715236  
Sum squared resid 0.001249 Schwarz criterion -8.671984  
Log likelihood 585.9208 Hannan-Quinn criter. -8.697660  
F-statistic 29492.60 Durbin-Watson stat 2.947218  
Prob(F-statistic) 0.000000

Prob = P-Value

**c) Test the null hypothesis that  $\beta = 1$  for the returns regression**

You can test other hypotheses, like for instance  $\beta = 1$ , via

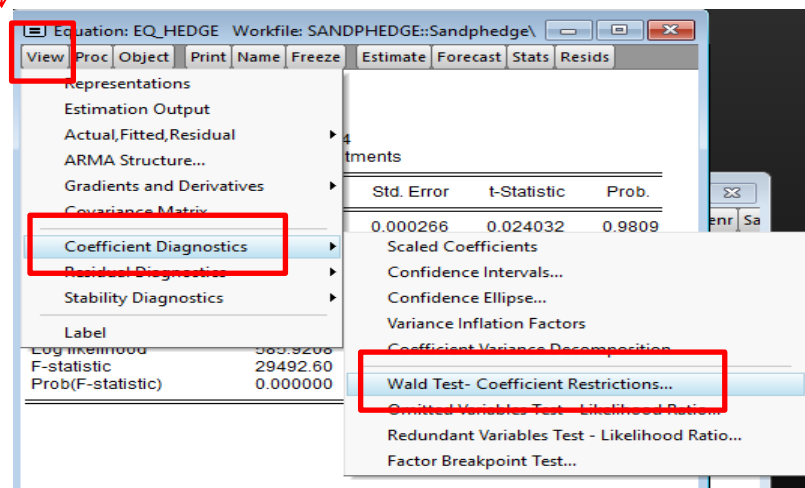

**Views\Coefficient Diagnostics\Wald Test - Coefficient Restrictions...**

The way Eviews deals with coefficients takes some getting used to. Eviews numbers all the coefficients, starting at the left and going to the right, so the equation

$r_s = \alpha + \beta r_f$  (error term omitted) will be interpreted by Eviews as

`rspot = c(1) + c(2) rfutures`

So to test whether  $\beta = 1$ , we will have to write **c(2) = 1** in the corresponding window.

Equation: EQ\_HEDGE Workfile: SANDPHEDGE::Sandphedge\

View Proc Object Print Name Freeze Estimate Forecast Stats Resids

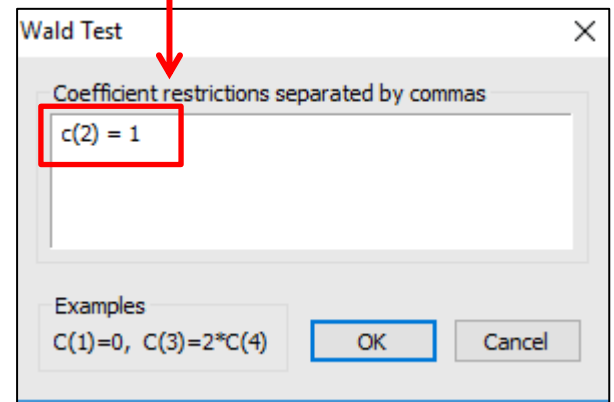

Wald Test:  
Equation: EQ\_HEDGE

Test Statistic	Value	df	Probability
t-statistic	1.243066	132	0.2160
F-statistic	1.545212	(1, 132)	0.2160
Chi-square	1.545212	1	0.2138

Null Hypothesis: C(2) = 1  
Null Hypothesis Summary:

Normalized Restriction (= 0)	Value	Std. Err.
-1 + C(2)	0.007291	0.005885

Restrictions are linear in coefficients.

**d) Interpret your results**

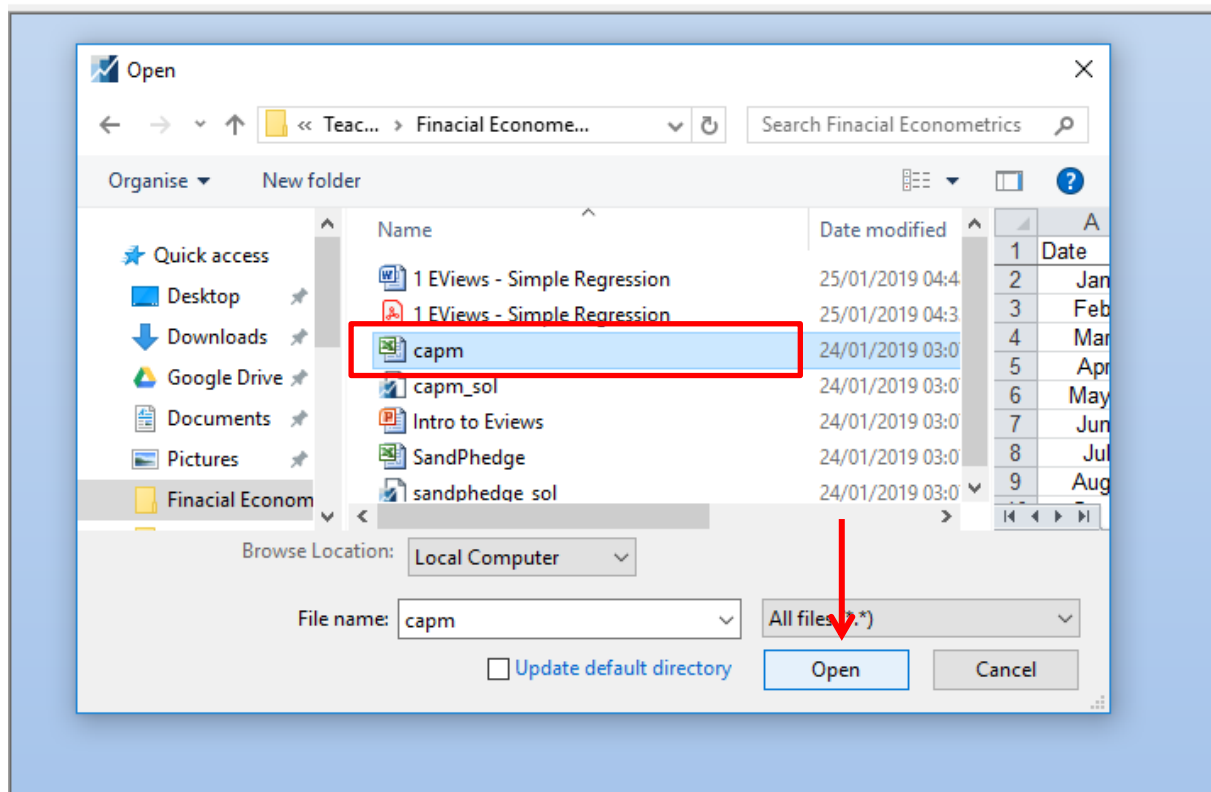

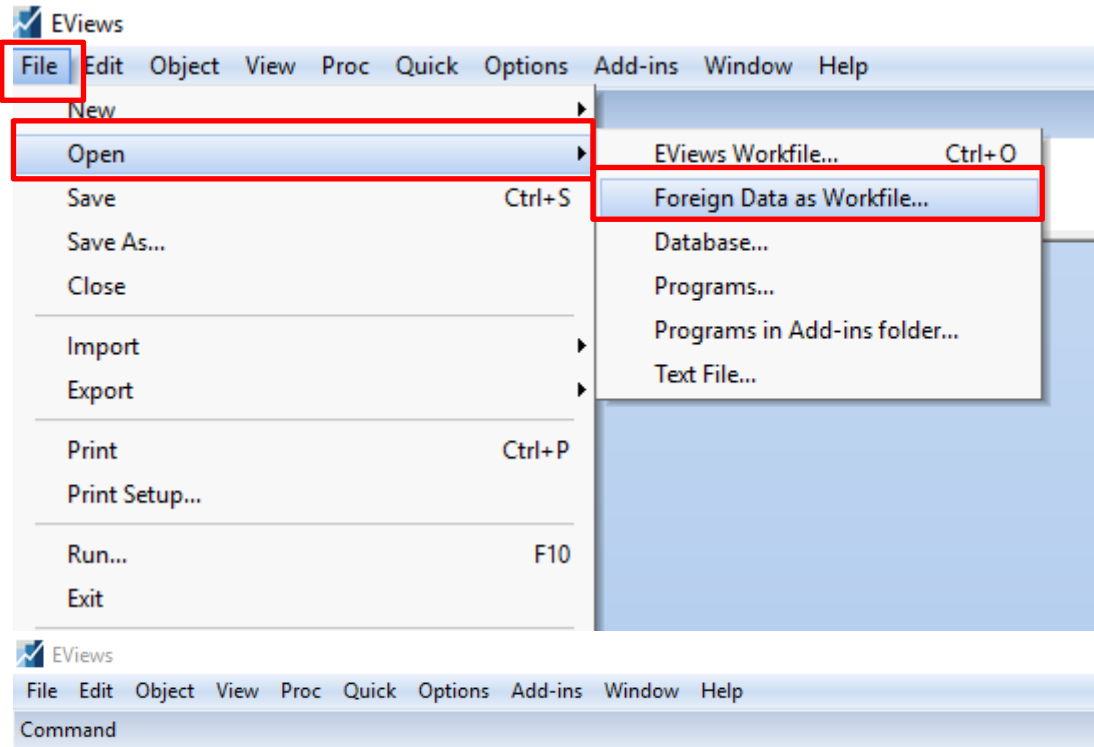

The hedge ratio is significantly different from zero, but not significantly different from one.

This is suggestive that: a) SandP futures are a good way to hedge spot returns and the optimal hedge ratio is close to 1.

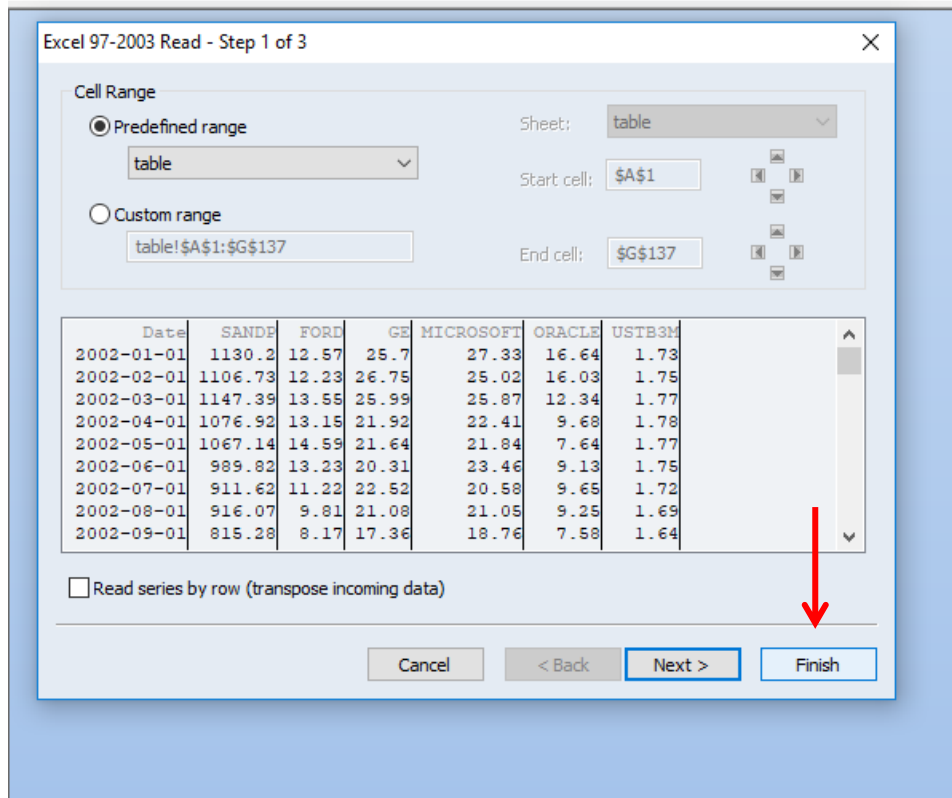

## Data Set 2: CAPM

### Task 1 Start Eviews and Import Data

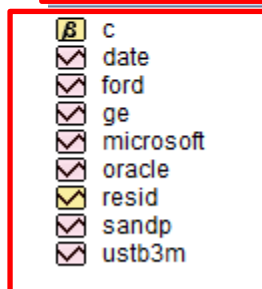

a) **Import** capm.xls

The Workfile will look like the image below:

- b) **Generate** new series to calculate the monthly risk-free rate and the log excess returns for the S&P 500 and Ford.

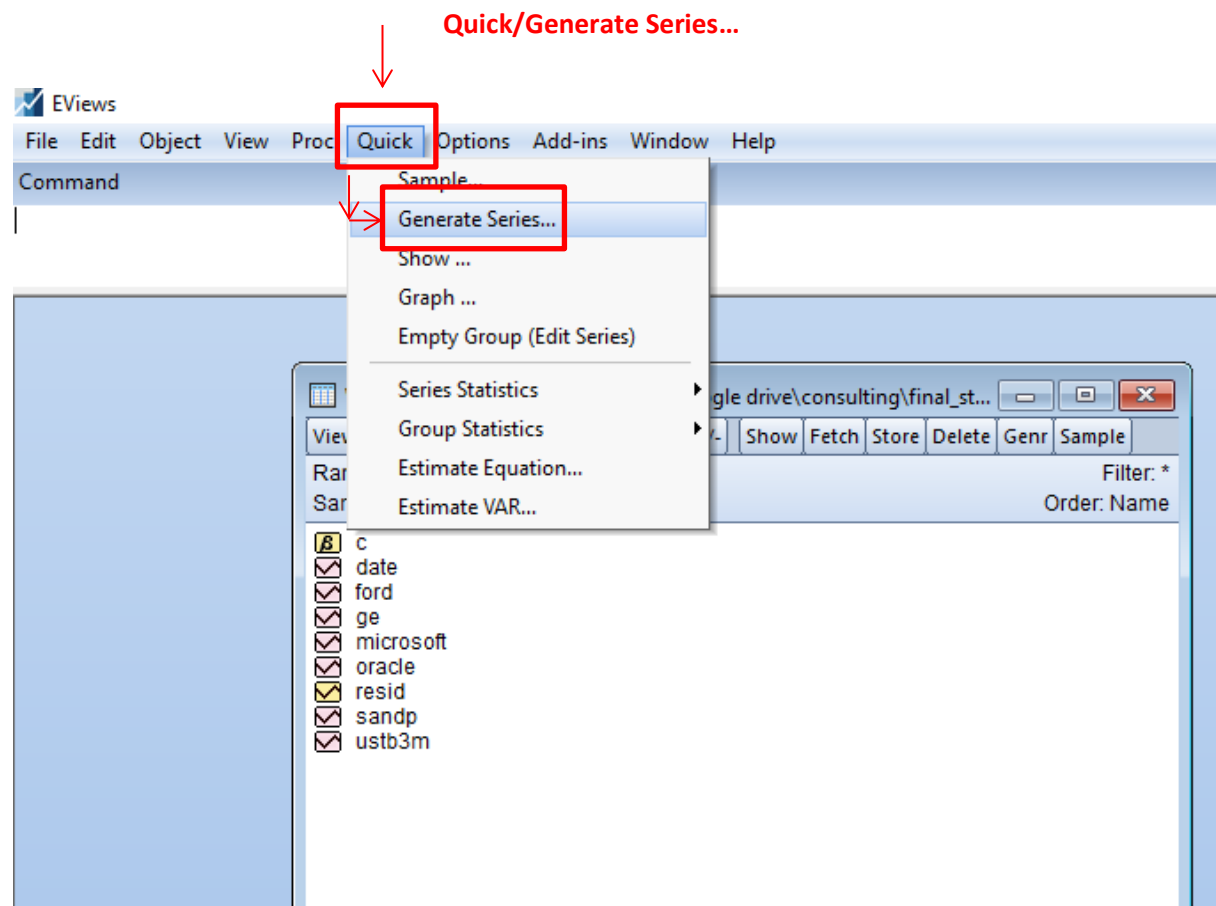

**Note that you need to be careful in how you transform the interest rates. 1) the tbill data is currently expressed annually, not monthly, and 2) the data is expressed in a way such that a value of 1 is interpreted as 1%. We would like to scale it so that 0.01 is interpreted as 1%. Thus you will have to divide the data by 12 to get monthly returns and by 100 to go from 1 to 0.01.**

Recall that the formula for log returns of an asset is

$$r = \ln(P_t) - \ln(P_{t-1}) = \Delta \ln(P_t)$$

An excess return is defined as a return less the risk free rate.

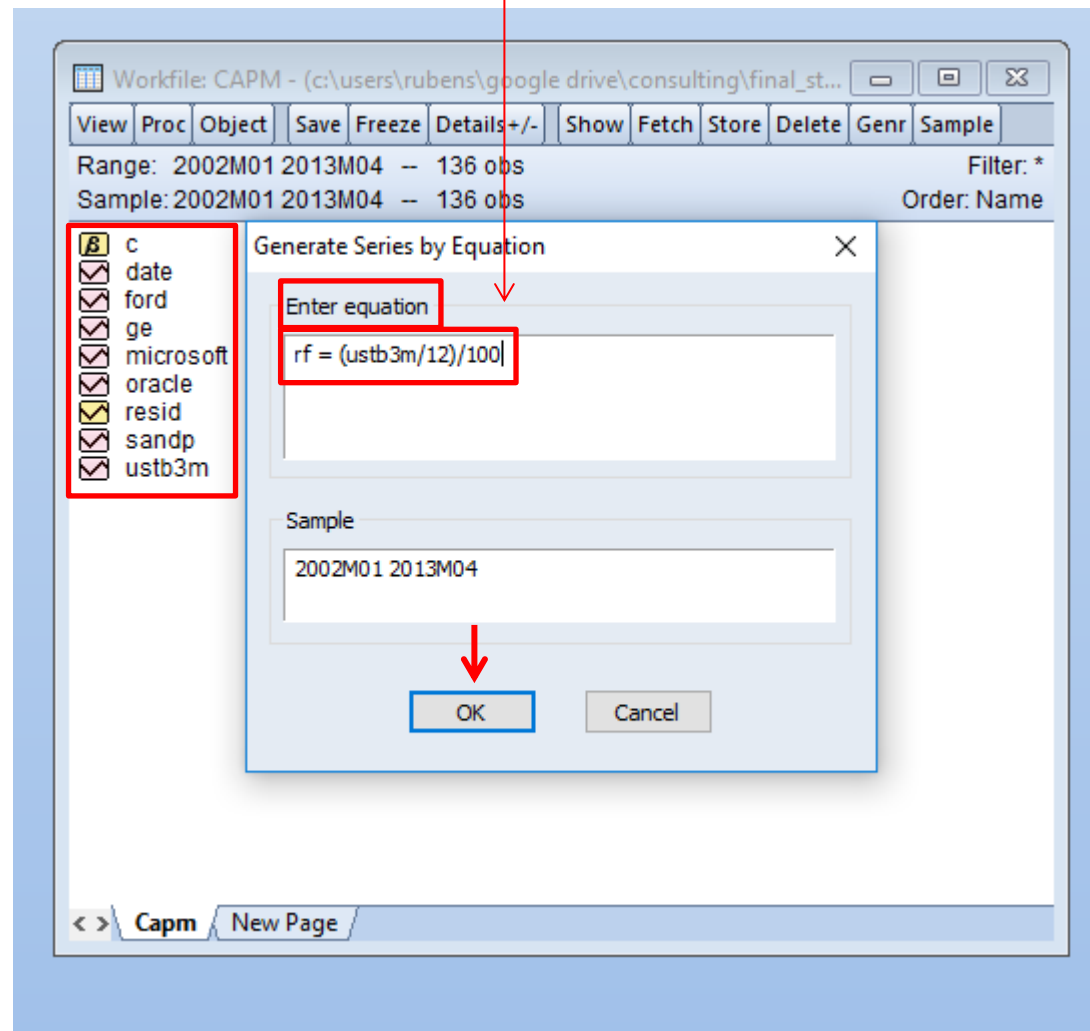

$$r_e = r_i - r_f$$

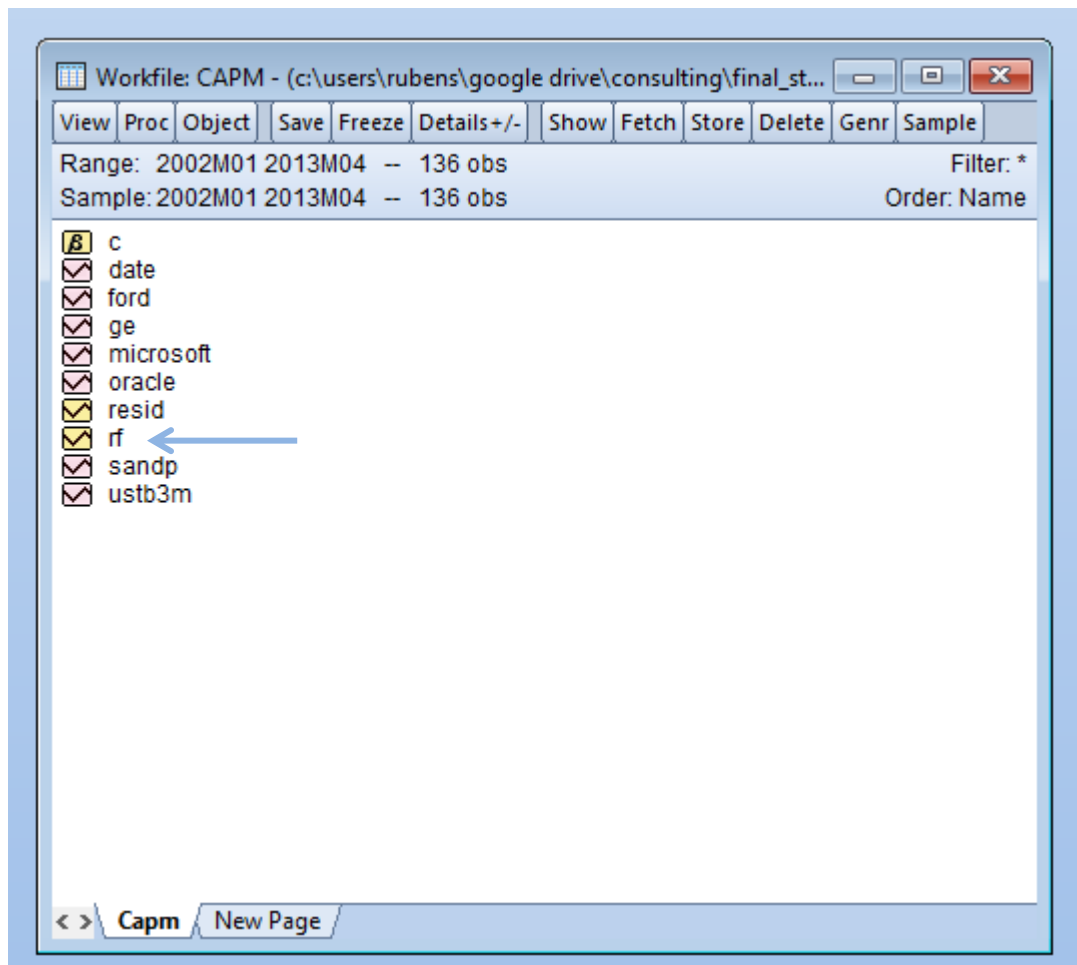

The formulas for each of the variables is given below.

Type the formulas inside the box **one by one** : Enter equation

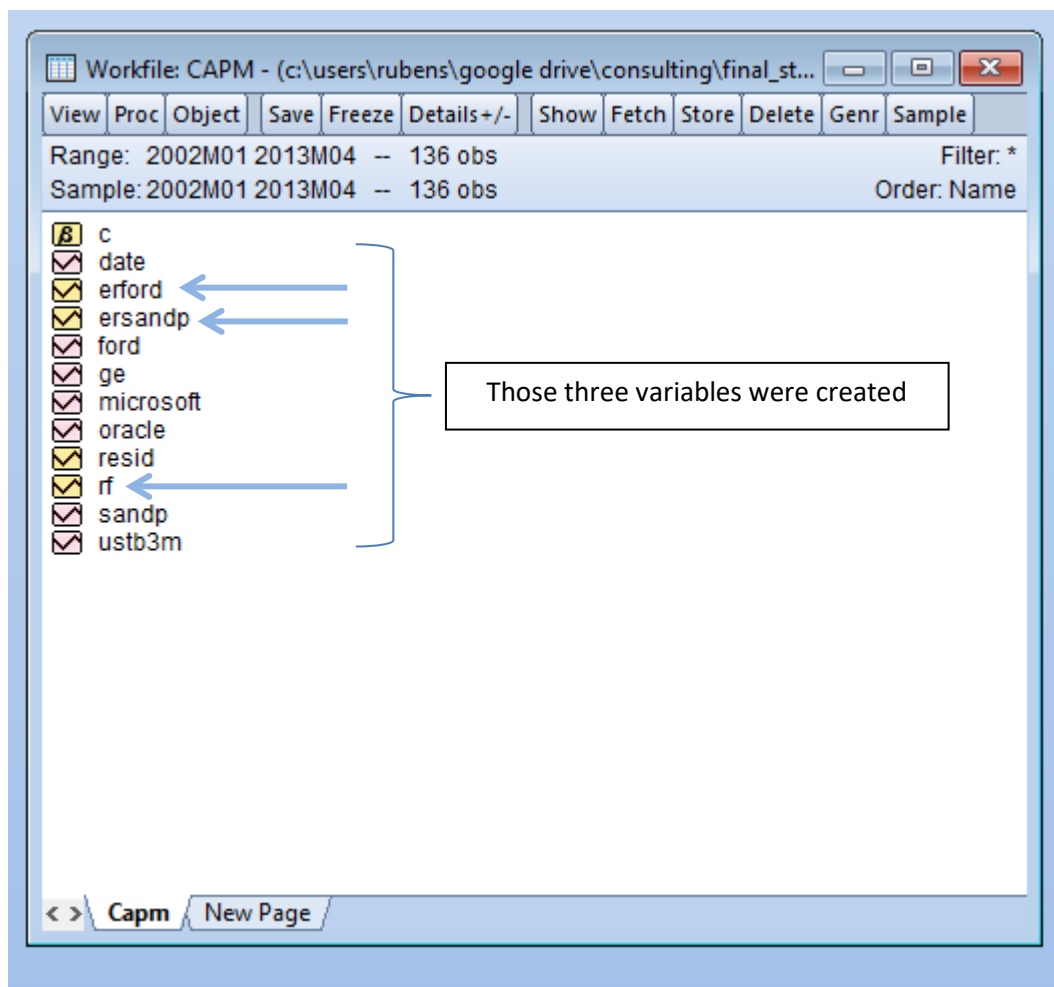

```
rf = (ustb3m/12)/100  
erford = dlog(ford) - rf  
ersandp = dlog(sandp) - rf
```

The new variable **rt** will be created and saved in the workspace.

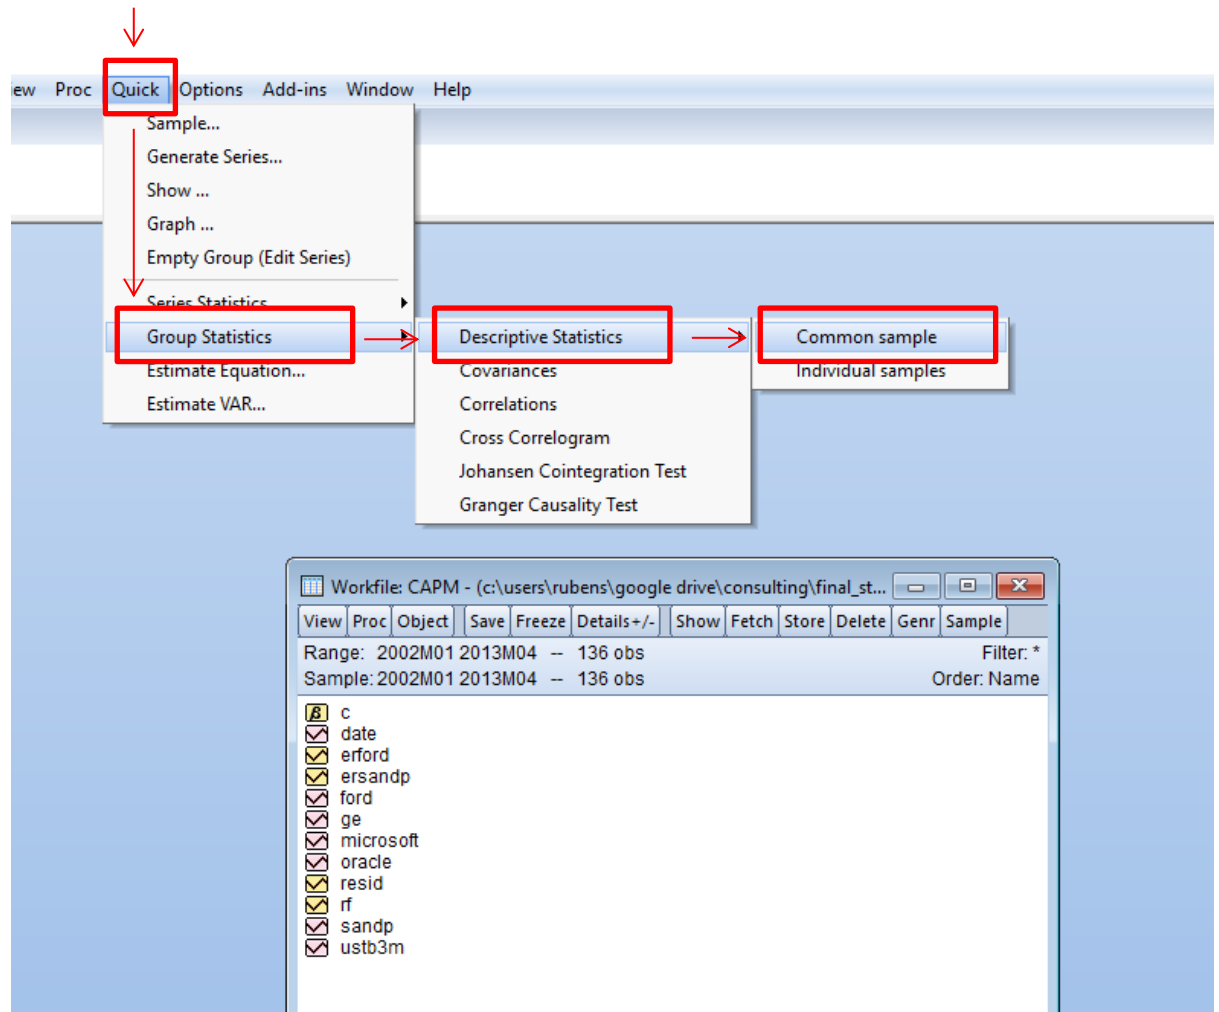

After typing all the formulas, your workspace will look like:

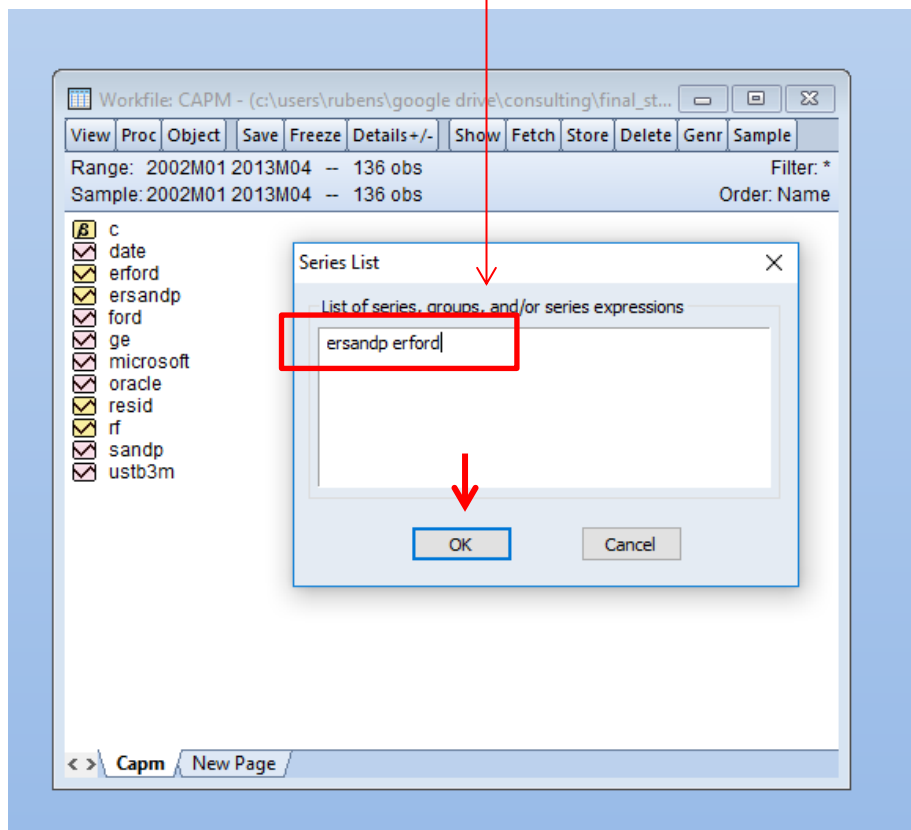

## Task 2 Descriptive Analysis of Data

a) Create a group

Quick\Group Statistics\Descriptive\Common sample

The following screen must appear to you. Then, inside the box called **Series List**, type:  
**ersandp erford**

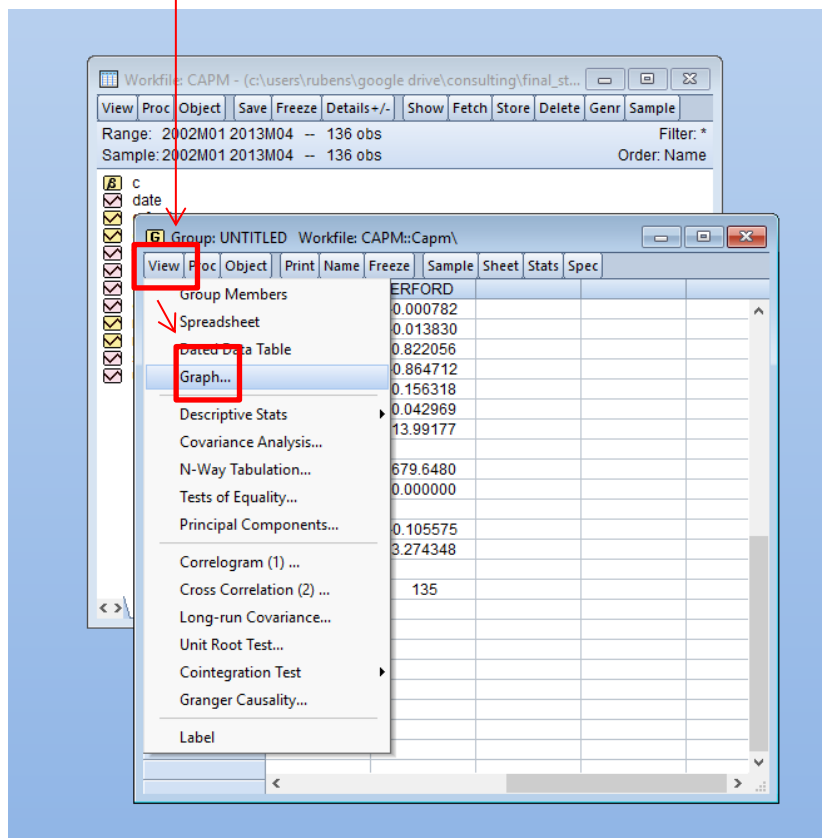

b) check the **descriptive statistics**

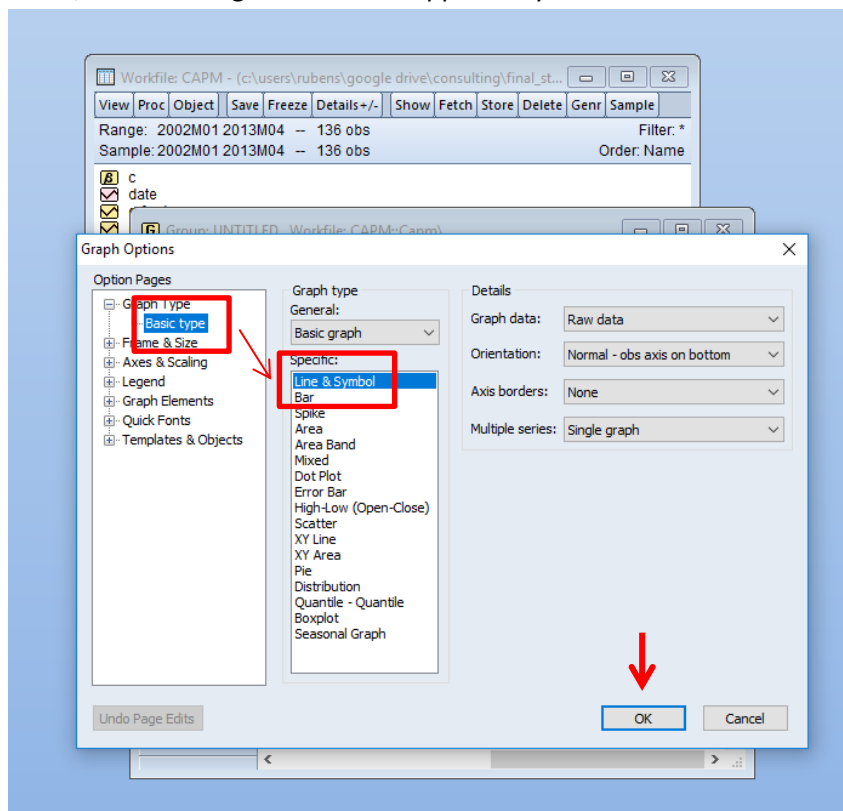

View	Proc	Object	Print	Name	Freeze	Sample	Sheet	Stats	Spec
				ERSANDP		ERFORD			
Mean				0.001193		-0.000782			
Median				0.008337		-0.013830			
Maximum				0.100639		0.822056			
Minimum				-0.184548		-0.864712			
Std. Dev.				0.045851		0.156318			
Skewness				-0.861999		0.042969			
Kurtosis				4.691981		13.99177			
Jarque-Bera				32.82171		679.6480			
Probability				0.000000		0.000000			
Sum				0.161010		-0.105575			
Sum Sq. Dev.				0.281715		3.274348			
Observations				135		135			

c) create line and scatter **graphs**

In **View/Graph**

Then, the following screem must appear to you:

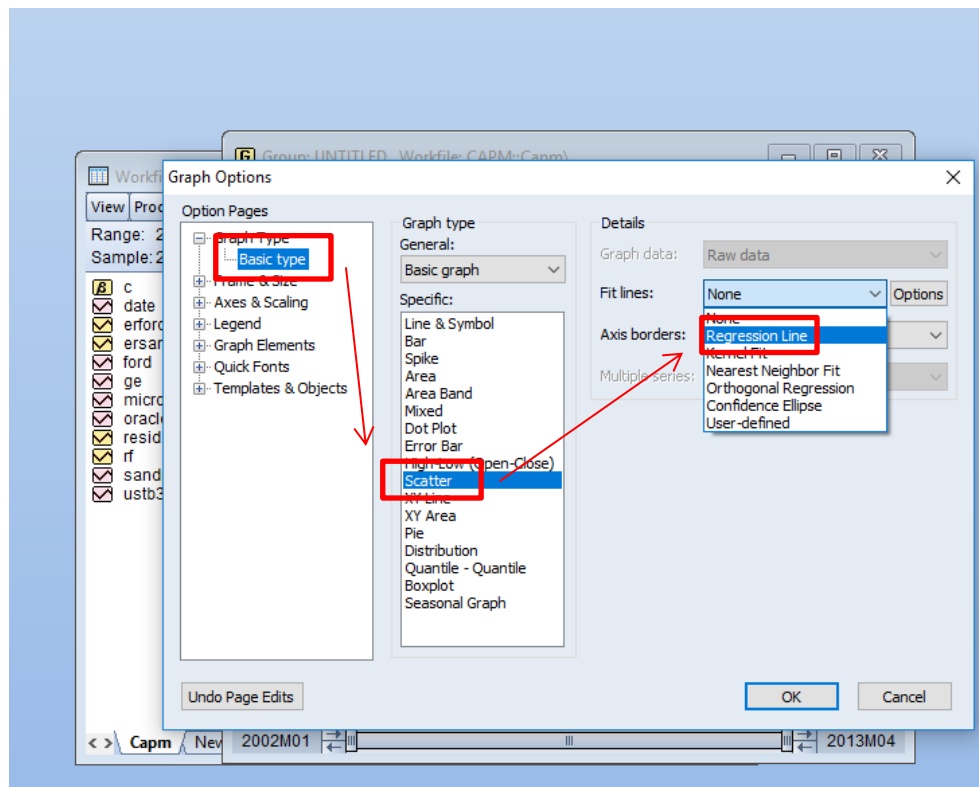

For the scatter we have:

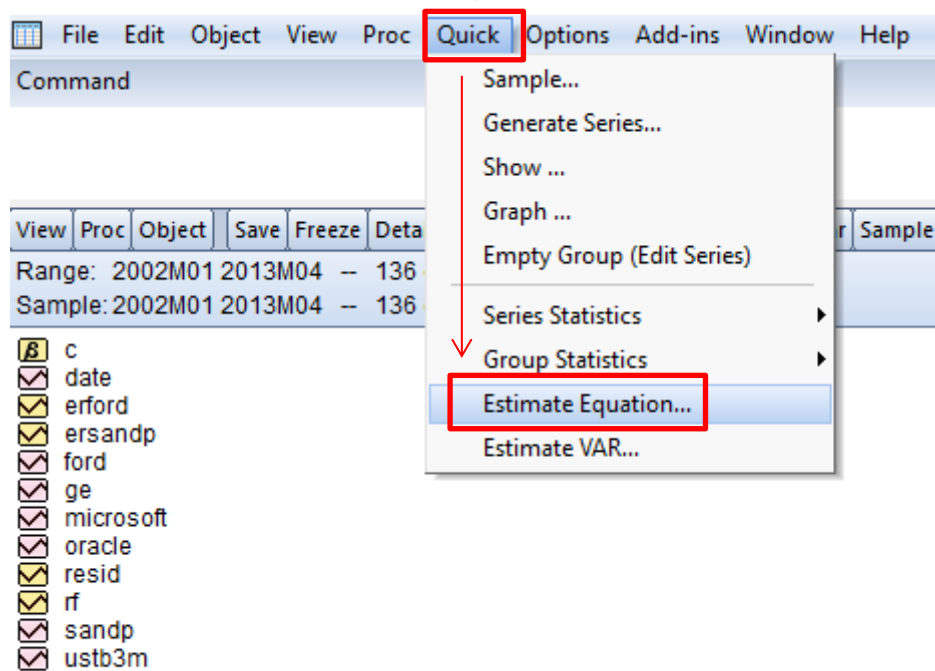

Just select a different type of plot

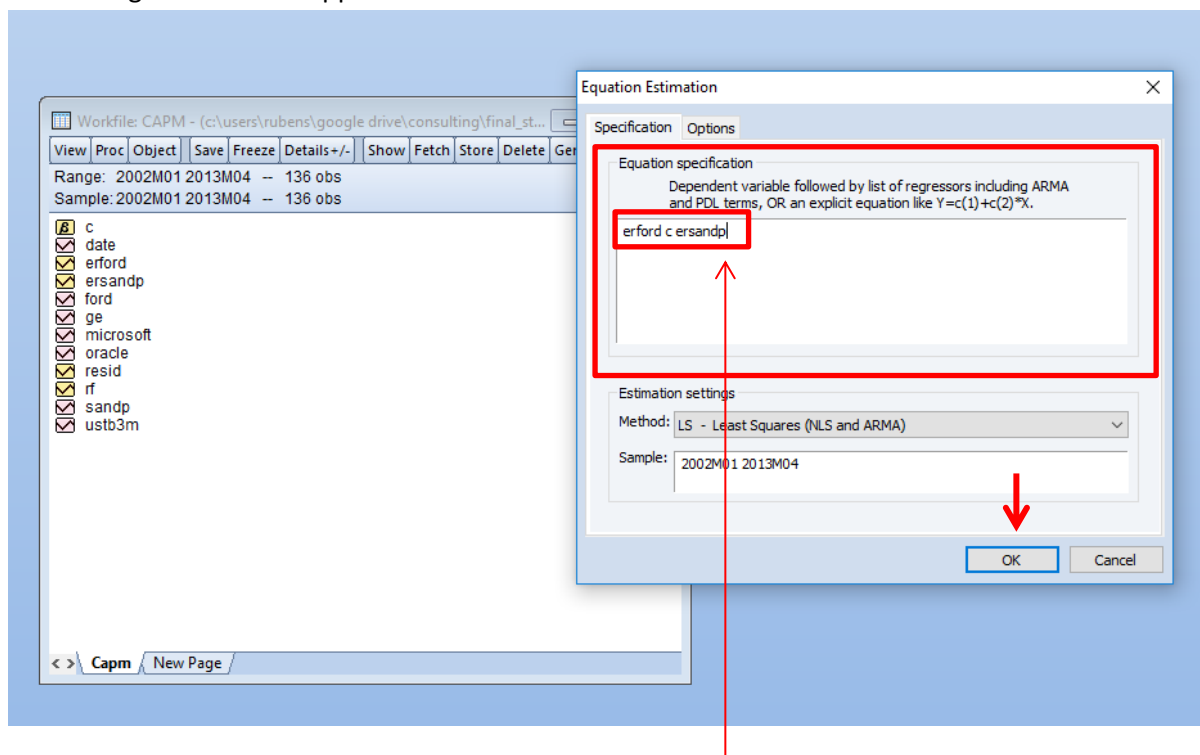

### Task 3 Calculating alpha and beta for Ford

- Estimate the CAPM regression for Ford, ie.  $(r_i - r_f) = \alpha + \beta(r_m - r_f) + \epsilon$
- In **Quick/Estimate Equation...**

A following screem must appear:

Inside the box, **Equation specification**, type: `erford c ersandp`

- c) **Test** the null hypothesis that  $\alpha = 0$  and  $\beta = 0$  for both the returns regression

Equation: UNTITLED    Workfile: CAPM::Capm\

ViewProcObjectPrintNameFreezeEstimateForecastStatsResids

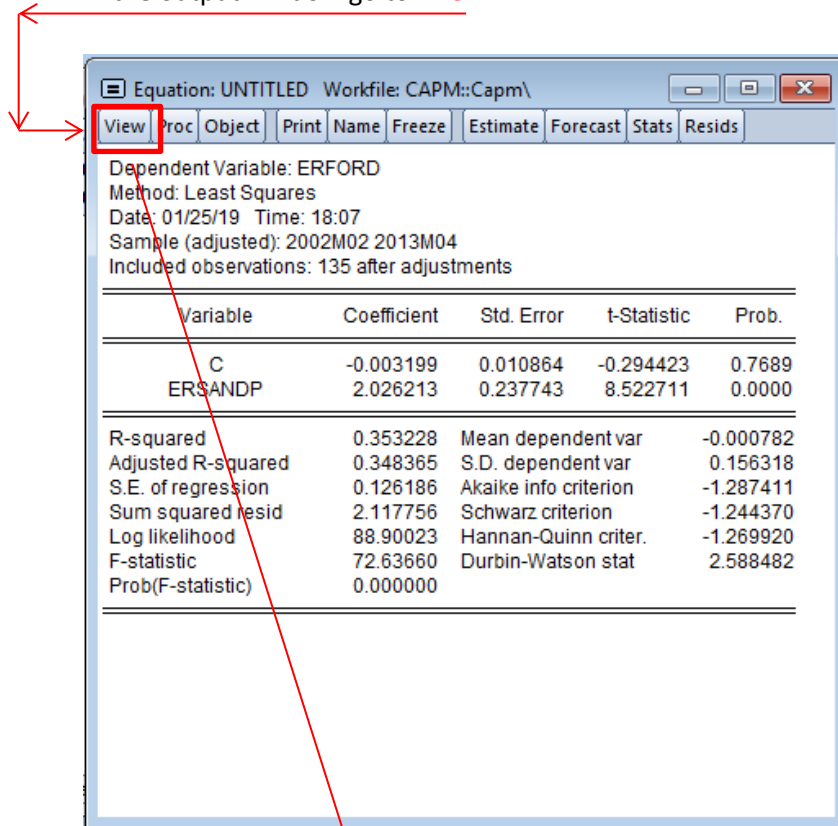

Dependent Variable: ERFORD  
Method: Least Squares  
Date: 01/25/19    Time: 18:07  
Sample (adjusted): 2002M02 2013M04  
Included observations: 135 after adjustments

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	-0.003199	0.010864	-0.294423	0.7689
ERSANDP	2.026213	0.237743	8.522711	0.0000

R-squared	0.353228	Mean dependent var	-0.000782	
Adjusted R-squared	0.348265	S.D. dependent var	0.156218	
S.E. of regression	0.126186	Akaike info criterion	-1.287411	
Sum squared resid	2.117756	Schwarz criterion	-1.244370	
Log likelihood	88.90023	Hannan-Quinn criter.	-1.269920	
F-statistic	72.63660	Durbin-Watson stat	2.588482	
Prob(F-statistic)	0.000000			

As can be seen in the output above, the intercept (alpha) is not significant from zero at the 5% level (pval 0.7689 > 0.05), but the slope coefficient (beta) is (pval 0.000 < 0.05).

- d) **Test** the null hypothesis that  $\beta = 1$  for the returns regression  
In the output window go to: **View**

Equation: UNTITLED Workfile: CAPM::Capm\

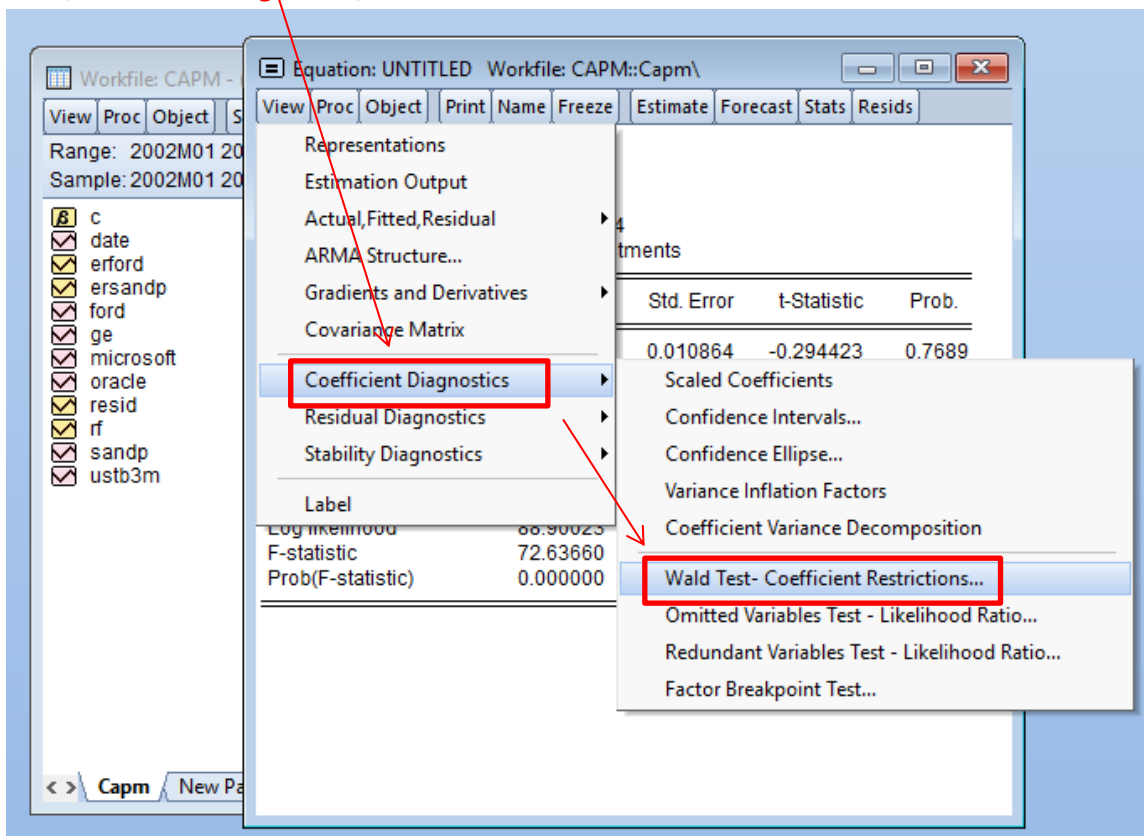

Dependent Variable: ERFORD  
Method: Least Squares  
Date: 01/25/19 Time: 18:07  
Sample (adjusted): 2002M02 2013M04

Log likelihood 88.90023  
F-statistic 72.63660  
Prob(F-statistic) 0.000000

Then, type:  $c(2)=1$  in the box called **Wald Test**

The output is:

The output below shows that the t-stat of the test of significance is lower than **0.05**, so reject the (two-sided) test that  $\beta = 1$ .

e) **Interpret** your results

- i. Are the coefficients significant?
- ii. Can the CAPM price Ford? (check the intercept)
- iii. Is there evidence that Ford is more or less risky than the market? (check the slope)
- iv. (Trickier) How much of the risk of Ford is idiosyncratic, how much is systematic? (check R2)

Alpha is not significant from zero, which could be interpreted that there is no evidence that Ford is either underperforming or overperforming.

Beta is both significantly different from zero and significantly different from 1, this implies that Ford is exposed to systematic risk (ie.  $\beta \neq 0$ ) and has systematic risk higher than the market (ie.  $\beta > 1$ )

The R2 measures which fraction of the variability of Ford can be explained by the market. It is 35% here, meaning that 35% of the movements of Ford can be explained by systematic factors. The other 65% is determined by firm-specific idiosyncratic factors (that is, assuming that CAPM is the right model)
